1.0 Introduction

During the period of January 14-18, 1985, the FAA conducted a noise monitoring program of helicopter operations at the Lakefront Airport in New Orleans, Louisiana. This is a companion report to a previous report which analyzed noise levels from helicopter operations in Las Vegas (Helicopter Noise Survey Performed at Las Vegas, Nevada FAA-EE-84-15). As in the previous analysis, the purpose was to obtain noise measurements from helicopter operations in an urban environment. The Las Vegas noise monitoring program conducted in 1984, focused primarily on helicopter takeoffs. In this program, the FAA concentrated solely on the approaches. In addition, this field measurement program afforded the FAA the opportunity to conduct a noise monitoring program in a residential area near concentrated helicopter operations.

The noise data collected are classified as survey type data, since the monitoring program's measurements data obtained were from "targets of opportunity" as opposed to a "controlled test" where the helicopters follow predefined flight path profiles. The helicopter flight corridors into and out of the departure and landing sites were prescribed by the airport operator to separate the helicopter operations from the fixed wing aircraft. However, there were no limitations placed on the helicopter pilots to control individual flight paths, rate of climb, rate of descent, airspeed, operational weight, etc. As such, the landings and takeoffs represent operations into and out of this particular site for the particular test day meteorological conditions.

During the testing period, there were ten different helicopter models monitored. Because of the high frequency of operations (i.e. an average of 15-20 per hr) the opportunity was provided to determine the consistency between maximum A-weighted sound level (ALM) values for the same helicopter model for different events, with variations in operations due to change in speed, glide slope, load, climb angle, pilot techniques, etc. within the prescribed flight corridor. This test also obtained sideline measurements of helicopter noise beyond 500 ft. The sites were located in established residential areas. This provided an opportunity to compare real time noise levels associated with a high frequency of helicopter operations in a nearby community. This report also contains noise measurements of helicopter models which are not in data bases previously reported by the FAA, notably the Bell 412 and Westland WG-30.

2.0 Noise Measurement Program

The FAA with support from Bell Helicopter Textron and Sikorsky Aircraft, conducted the noise measurement program. The test plan, developed and implemented by the FAA, laid out the conceptual approach for locating the monitoring sites and the objectives to be achieved. Industry participation consisted of providing coordination with helicopter traffic control and noise measurement crews who worked under the guidance of the FAA and supplemented the FAA's measurement crew. With industry's assistance it was possible to deploy two noise monitoring stations in the residential area adjacent to Lakefront Airport.

The noise data collected were from helicopters during their final approach into Lakefront Airport. An array of microphones were set out to measure noise from the helicopters in the approach flight corridor. One microphone was located beneath the approach path while the other three were located to the left and normal to the approach path of the helicopters.

3.0 Site Description

Lakefront Airport is located approximately 5 miles northeast of downtown New Orleans on the southern edge of Lake Pontchartrain. The area is relatively flat with winds predominately from the northwest during the winter season. Lakefront Airport is principally a general aviation airport with 221,264 operations during 1984. Figure 1 shows the layout of the airport. The HAI flight line was located on the southeast corner of the airport occupying runways 31 and taxiway Echo. The Lakefront control tower controlled both the helicopter traffic for the HAI Convention and the general aviation activity at the airport.

South of the airport is a levee which is approximately 20 ft in height. The levee is part of the flood protection system which protects the City of New Orleans from Lake Pontchartrain. The levee at this location also serves as a railroad right-of-way with the tracks on top of the levee. Beyond the levee south of the airport is a residential community of single family detached homes. This area has been designated as a noise sensitive area by the airport operator. Aircraft operating at Lakefront are instructed to avoid flying directly over this area when feasible. The

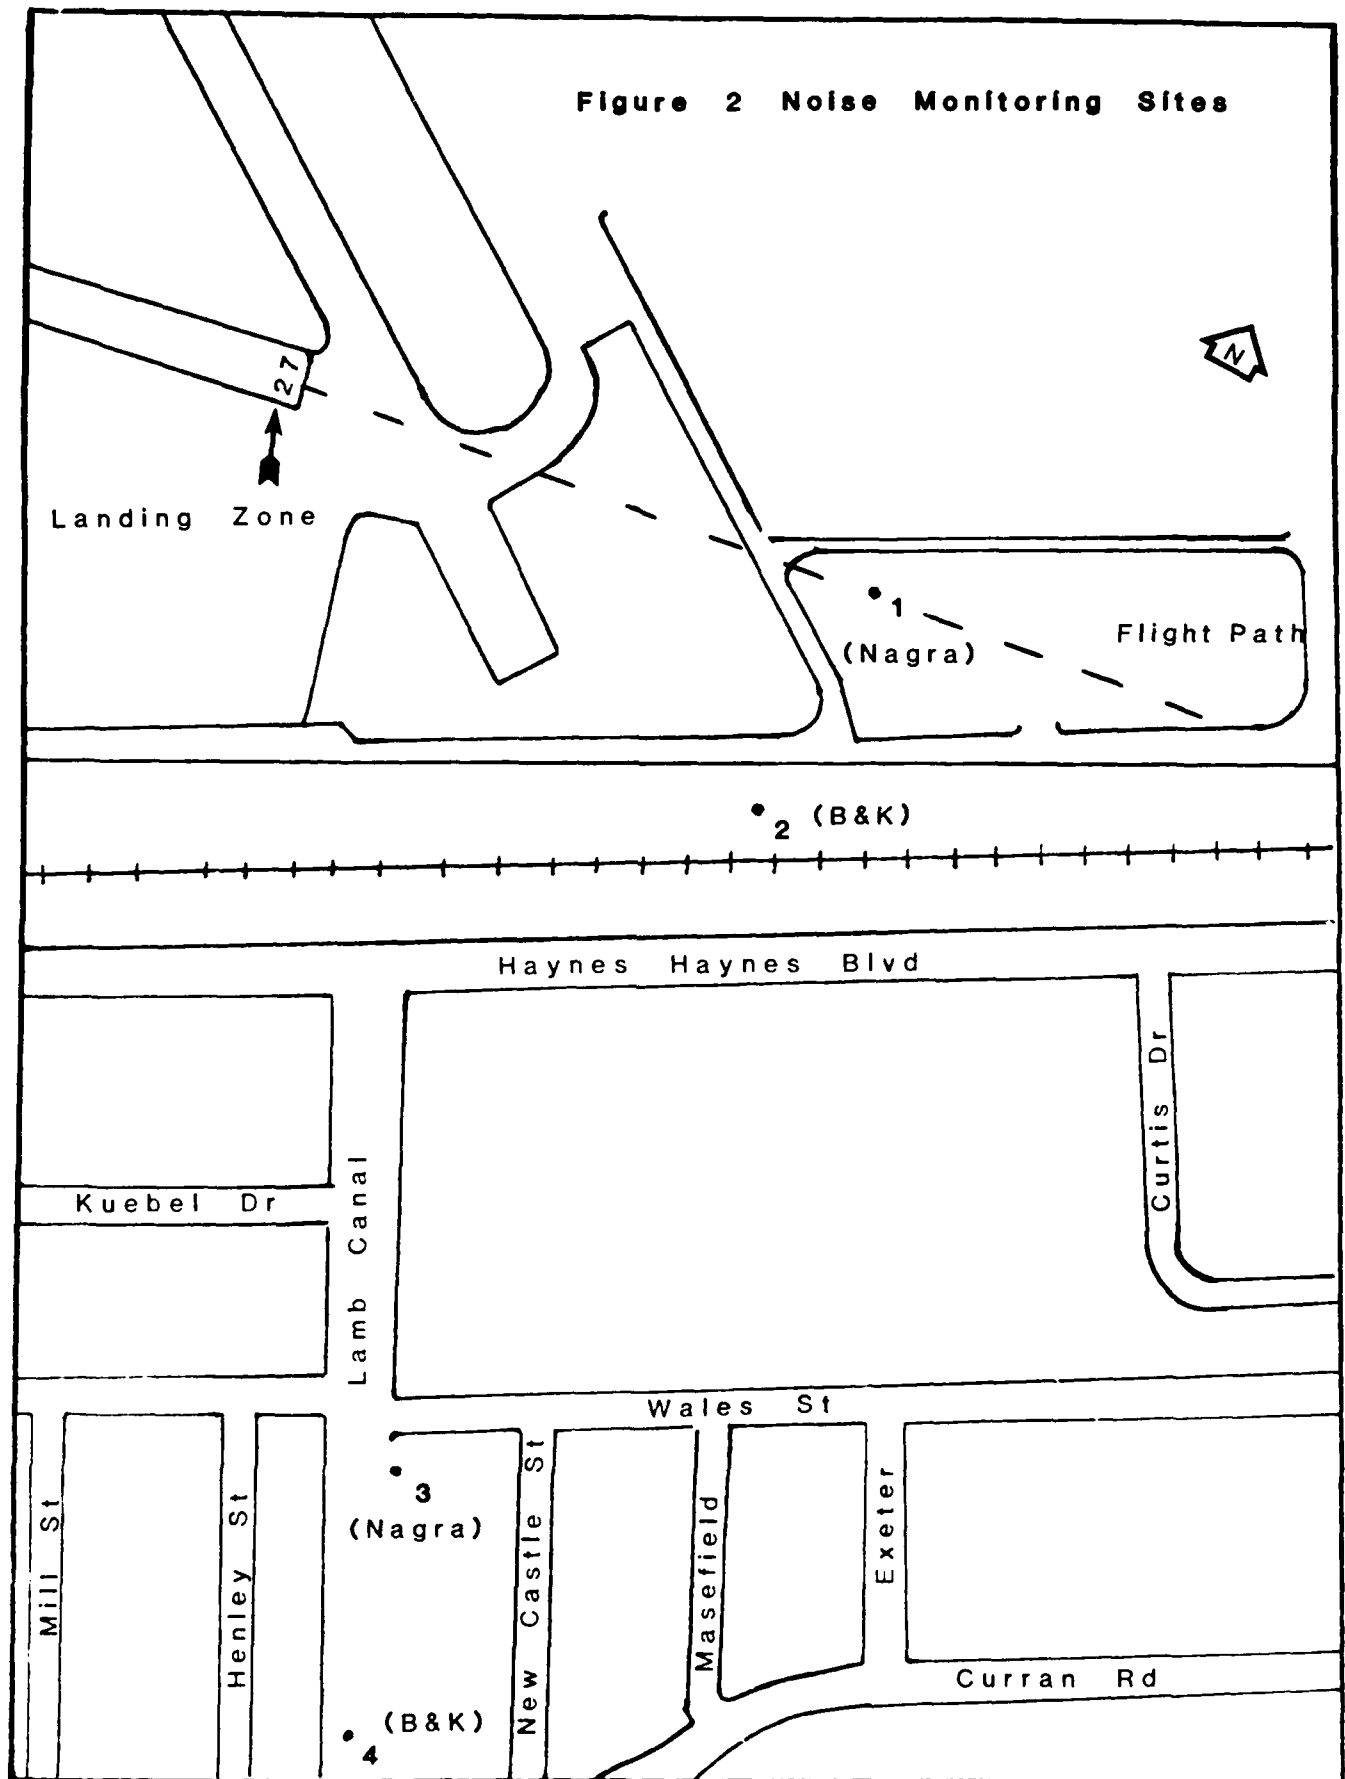

Figure 1 Lakefront Airport
New Orleans

helicopters approached the airport from the east by following Haynes boulevard which runs parallel to the noise sensitive area. Since the airport has received several noise complaints from residents in this area from aircraft flying over their neighborhood, the FAA was afforded the opportunity to measure noise in the community from the helicopters during approach to the airport while gathering information with respect to any noise complaints attributed to the helicopter fly-bys during approach.

4.0 Microphone Deployment

Figure 2 shows the respective locations of the noise monitoring stations. Site 1 which was designated the centerline center microphone was located at a distance of approximately 790 ft from the designated landing zone. Site 2 was located 325 ft; site 3, 1455 ft; and site 4, 2410 ft to the southwest of the centerline microphone. All of the sites were located on a grassy surface. Site 2 was situated on the airport grounds approximately 30 ft from the railroad right-of-way. The railroad right-of-way was used infrequently during the measurement program and therefore did not result in any loss of data due to noise interference. Sites 3 and 4 were located in a residential area to obtain measurements of the helicopters in relation to existing ambient conditions. Between sites 2 and 3 adjacent to the levee there is a four lane highway. Traffic volume during the testing was relatively light with the majority of the vehicles consisting of automobiles. The only physical barriers in the line of sight between monitoring sites 3 and 4 and the landing zone are one story houses and the 20 ft levee. These barriers created some shielding during the near-hover operation over the landing area and during

Figure 2 Noise Monitoring Sites

air taxiing to the landing spot.

5.0 Flight Operations

The flight line for the HAI Convention was located at Lakefront Airport. The helicopters departed from mid-field toward the north over Lake Pontchartrain turning to the east heading to the demonstration area. On returning to Lakefront Airport, when the helicopters were within approximately 2 miles of the airport, the pilots were instructed to fly parallel to Haynes Boulevard during their final approach to the numbers at the end of runway "27". The helicopters slowed to a near-hover over the designated landing zone "27". Then they air taxied to their designated landing spot.

6.0 Meteorological Conditions

Weather conditions were quite suitable for noise monitoring during the measurement program, that is, the skies were clear and the winds were light. A self-contained onsite meteorological system was deployed near the centerline microphone to monitor real-time temperature, wind speed, and wind direction. The surface temperature as measured from this system ranged from 40° to 50°F during the the three-day monitoring program. The winds were principally from the west, northwest, or north at an average speed of 7 mph. On a few occasions, the wind direction swung around to the southwest. Meteorological conditions during the test period did not affect the standard landing operations of the helicopters.

7.0 Instrumentation

7.1 Noise Monitoring Equipment

The following equipment was used at different times during the noise monitoring program, B&K Model 2233 and Model 4165 Precision Integrating Sound Level Meter (PISLM), Gen Rad 1945 Community Noise Analyzer, and NAGRA IVSJ magnetic tape recorder. A Nagra and B&K 2233 PISLM were located at site 1, a B&K 2218 PISLM was used at site 2, another Nagra and the Gen Rad 1945 were deployed at site 3 and a B&K 4165 was used at site 4.

The B&K systems used a 1/2 inch condenser microphone. The system is self-contained in that the microphone was directly attached to the PISLM. Output was observed on an analog scale and digital read out on the PISLM. The Gen Rad 1945 used a P-42 microphone-preamplifier driving a Gen Rad 1/2 inch electret microphone. The microphone preamplifier assembly was mounted on a tripod four (4) ft above ground level with the diaphragm oriented for grazing incidence.

At the end of each event, the observers noted the digital read out of the ALM (Maximum A-weighted Sound Level); Leq (Equivalent sound level); SEL (Sound Exposure Level); and the duration of the event. Measurements made with the Gen Rad 1945 were digitally outputted on an LED screen and at the end of the sampling period, the Leq values were annotated on the chart paper. The observers were located 20-30 ft from the microphone to avoid any shielding or interference.

The NAGRA IVSJ recorder analog signal was amplified to a suitable recording level and was recorded on channel one. A time code was recorded on the queue channel for traceability of events. The queue channel was also used by the observer to annotate the tape orally. The magnetic tapes recorded by the FAA were later reduced and analyzed at the FAA Noise Lab at Dulles International Airport. The magnetic tapes recorded by Bell and Sikorsky were reduced and analyzed at the Bell Helicopter Textron Acoustic Lab.

7.2 Photographic Scaling

Centerline altitude for the helicopters were determined according to SAE Aerospace Information Report 902. Each helicopter was photographed as it passed over the centerline center microphone position. The image in each photo was then scaled to the dimensions of the helicopter to determine the altitude of the helicopter at that point in its approach. Even though the helicopters did not always pass directly over the centerline position, an error of 27 degrees in the angle between the line of sight and the normal to the flight path would only result in a 1 dB SPL.

8.0 Discussion of the Data

8.1 Sample Size

During the three day monitoring program, there were 108 approach events. The data recovery (Table 1) for each site based on ALM readings is as

Table 1
Data Recovery for the New Orleans
Helicopter Noise Monitoring Program
at Lakefront Airport
(Percent)

| Site (Distance from Centerline, ft) | Percent Recovered | | Percent Recovered | |
|---|-------------------|---------------|---|------------|
| | ALm Values | SEL Values | For Those Events That Passed Over Centerline | |
| | | | ALm | <u>SEL</u> |
| 1 (0) | 87 | 69 | 100 | 79 |
| 2 (354) | 73 | 43 | 77 | 40 |
| 3 (1455) | 67 | 21 | 73 | 7 |
| 4 (2410) | 46 | 0 | 52 | 0 |

follows: Site 1, 87%; Site 2, 73%; Site 3, 67%; and Site 4, 46%. Sites 1 and 2 had the highest percentage of valid readings. These sites had the least amount of noise interference. The loss of data at sites 1 and 2 was the result of interference due to routine vehicular and aircraft ground activity in the vicinity of the noise monitoring sites. The lower data recovery at sites 3 and 4 was due primarily to the relatively low signal-to-noise ratio and interference from community activity (i.e. automobiles, children playing, fly-bys from the airport, etc).

The data recovery based on SEL values is significantly lower than the AL_m values especially for sites 3 & 4 which were located off the airport grounds. In order to have a valid SEL, the noise from the helicopter has to be 10 dBA higher than the existing ambient. Site 3 located at a distance of 1455 ft had a SEL data recovery of 7% while Site 4 recorded no valid SEL readings at a distance of 2410 ft. The nearness of sites 1 and 2 to the approach flight corridor enabled these sites to have a much higher data recovery than the two farther sideline sites. However, even site 2 lost a considerable amount of data at an average slant range distance of 375 ft from the glide slope. Loss of valid SEL readings at the two close-in sites is attributed to noise interference.

At the farther distances from the source of noise, it is hard to identify clearly the helicopter noise from other sources of noise. It is extremely difficult to record valid SEL readings at distant points from a noise generator. In actuality the helicopter noise is not lost data, but is part of the ambient. Very few events were lost due to equipment malfunction. The first five events were disregarded as they were used to

determine the range settings for the equipment.

Since the noise measurements were targets of opportunity, the helicopters did not necessarily always pass directly over the centerline microphone. In the evaluation process, events were screened to delete those outside certain criteria (i.e. when helicopters during their final approach to the designated landing zone did not pass over the centerline microphone). Of all the approach events recorded, 48 passed over the centerline microphone. It is these events which were considered for further evaluation and analysis in section 8.2. The data recovery for these 48 events is as follows: site 1, 100%; site 2, 77%; site 3, 73%; and site 4, 52%. The remaining helicopter approaches were too far left or right of the centerline microphone to be considered for any further analysis.

8.2 Evaluation of the Data

Table 2 presents the recorded ALM readings as measured for the centerline and sideline sites for those events where the helicopter passed directly over the centerline microphone. In addition, the sideline elevation angles, and the absolute decrease in dBA between the centerline reading and sideline sites are presented. The ALM values as recorded at the centerline microphone from all the helicopters ranged from 80.8 to 96.4 dBA. The highest recorded noise level of 96.4 dBA at the centerline microphone was associated with the Westland WG-30, which passed by at an altitude of 152 ft. The lowest reading was 80.8 dBA associated with the A-Star which flew by at an altitude of 231 ft. The average ALM readings for each helicopter type at the centerline microphone ranged from 85 to 91 dBA.

| 18.24 | Twin Star | 94.1 | 30.4 7.5 4.5 | 0.70 16.50 20.50 |
| 19.03 | Twin Star | 92.2 | 77.8 27.3 6.6 4.0 | 1.90 17.70 NA |
| 18.29 | WG-30 | 104.6 | 81.1 25.1 6.0 3.6 | 10.40 26.70 27.40 |
| 18.73 | WG-30 | | 84.7 37.6 9.7 5.9 | NA 9.00 17.60 |

Because of the variance in the helicopter altitudes during each pass the centerline ALm noise readings were adjusted to a reference altitude. The reference altitude (R_0) of 182 ft is the average altitude of all the valid centerline noise measurement events. The adjustment of ALm was based on the relation of $22 \log(R/R_0)$ which approximates attenuation associated with spherical spreading and atmospheric absorption. There are other propagation factors which have not been accounted for, most notably source directivity, ground effects, and individual helicopter performance characteristics (i.e. RPM and power level). Table 3 is similar to Table 2, however, it provides statistical information for each helicopter measured. Also presented is the centerline ALm readings adjusted to the reference altitude (182 ft). The ALm values for the sideline sites were not adjusted since analysis of the sideline distances indicates that for distances of 1455 and 2410 ft from the centerline, the slant range distances did not change significantly between events.

In general, the data demonstrate that the noise level is fairly consistent between the various helicopter models and multiple flights of the same model. This is best shown by the standard deviation and 90% confidence level as presented in Table 3. The B-222UT showed the most consistent readings with an average ALm of 89.8 ± 1.23 dBA. The 500-E, which had the most recordings, showed a strong consistency between events with an average of 89.2 ± 1.86 dBA. The Dauphin and the WC-30, however, showed a greater spread in the data. Possible causes for this variation are numerous. Table 4 presents a summary of the standard deviations for each helicopter and the 90% confidence intervals for the centerline line center position. The average standard deviation for all the events is ± 2.05 dBA.

Table 4

Summary of the Standard Deviation
of Adjusted ALm and the 90% Confidence Interval by Helicopter
at the Centerline Center Location
(dBA)

| Helicopter | Standard Deviation | 90% Confidence Interval |
|------------|-----------------------|-------------------------------|
| 500 E | 1.9 | 1.1 |
| 530 F | 1.3 | 0.9 |
| AStar | 2.0 | 1.9 |
| B-206L3 | 0.7 | 1.3 |
| B-222UT | 0.7 | 0.8 |
| B-412 | 1.5 | 1.8 |
| Dauphin | 2.8 | 2.3 |
| Twin Star | 1.6 | 1.2 |
| Average | 1.6 | 1.4 |

Table 5 presents the sideline ALM values as recorded, the slant range, and elevation angle for the sideline sites for only those events where there were valid ALM readings at all four monitoring sites. The small number of events demonstrates the difficulty in obtaining clear signals at four distant sites on a real time basis. There was very little variation in the slant ranges between helicopter events. The average elevation angle at Site 2 was 26.9° ; Site 3, 6.6° ; and Site 4, 4.0° . The ALM decreased significantly from the centerline values which reflects the distance and attenuation attributed to ground and atmospheric absorption. Figure 3 shows graphically the decrease in sideline ALM values between sites 2 and 4 for the 500E, ASTAR, B-222UT, B-412, Dauphin, Twin Star, and WG-30. The graphical presentations of sideline distances vs ALM readings are based on the average of all the readings available for each helicopter model. A second order regression of ALM vs slant range distance resulted in a correlation coefficient of 0.93. Closer scrutiny of the data indicates that for the 500-E the ALM reading at 2410 ft was 1 dBA greater than the value recorded at the closer-in site at 1455 ft. The increase of 1 dBA is not considered significant and can be possibly attributed to several factors such as directivity, ground reflection, attenuation, etc. Of greater importance is that the ALM values in all cases appear to approach the ambient noise levels for this area, since the helicopters were barely distinguishable at these distances. From a practical environmental standpoint, the noise associated with helicopter operations at a heliport would not significantly affect the ambient noise levels at 1500 ft or beyond in a suburban residential area.

Table 5

ALM VALUES FOR THOSE HELICOPTERS WHERE THERE WERE READINGS AT ALL THREE SIDELINE SITES

| Event Number | Helicopter | Slant Range for Noise Monitoring Stations | | | ALM (dBA) for Each Site | | | Elevation Angle for Each Site (Degrees) | | |
|-----------------|-----------------|--|------|------|----------------------------|-------|-------|---|-------|-------|

Figure 3 ALM vs Slant Range Distance

8.3 Community Noise

In addition to measuring the ALM and SEL values, a community noise analyzer was deployed during the monitoring program. Hourly readings during the test period indicated that the Leq value ranged from 58 to 60 dBA. These samples included on the average 20 helicopter operations including approaches, takeoff, and flybys at Lakefront. Figures 4 and 5 show the relation of helicopter noise and the existing ambient levels. It is clearly shown that at a distance of approximately 1500 ft. and beyond from the centerline microphone, the noise associated with the helicopter was barely above the ambient levels. Other sources of noise in the community showed ALM readings ranging from 58 to 66 dBA for cars and trucks and 72 dBA for buses. During the three day monitoring period when there was a high number of helicopter operations, there were no known noise complaints received at the airport due to the operations from the helicopters based at the airport for the the HAI Convention.

9.0 Summary

The FAA conducted a field noise monitoring program of helicopter operations at a busy general aviation airport. The purpose was to collect helicopter noise data as a continuing effort from the FAA to assess helicopter noise in different urban areas. The data collected emphasized landing approaches and indicated that there was a consistency between the noise levels measured for each helicopter model. The FAA had the opportunity to evaluate the potential impact of a high frequency of helicopter events in a residential community adjacent to a heliport.

Figure 4 Time History of Selected Noise Events
at Site 3

Figure 5 Time History of Selected Noise Events
at Site 3

During the test period there were no known noise complaints received at the airport from the helicopter operations. In this case, the helicopters did not appear to impact significantly sites 1500 ft away. The lower data recovery, specifically SEL, at monitoring sites in the community reflects this fact. In most instances, this was due to the fact that the noise levels from the helicopters were barely distinguishable from the existing ambient noise levels at distances of 1500 ft and beyond.

Appendix A

Selected Specifications of Helicopter Types
Monitored During the Test

Aerospatiale 355 F Twin Star

| | |
|---------------------|------------------------------------|
| Power Plant | (2) Allison 250C-20F, 420 shp each |
| Main Rotor Diameter | 35.1 ft |
| Tail Rotor Diameter | 6.1 ft |
| Empty Weight | 2840 lbs |
| Gross Weight | 5071 lbs |
| Height | 10.1 ft |
| Length | 42.6 ft |
| Width | 6.9 ft |

Aerospatiale AStar

| | |
|---------------------|---|
| Power Plant | (1) Avo Lycoming LTS 101-600A2, 615 shp |
| Main Rotor Diameter | 35.1 ft |
| Tail Rotor Diameter | 6.1 ft |
| Empty Weight | 2,432 lbs |
| Gross Weight | 4,300 lbs |
| Height | 10.3 ft |
| Length | 42.6 ft |
| Width | 6.9 ft |

Aerospatiale Dauphin

| | |
|---------------------|--------------------------------------|
| Power Plant | (1) Turbomeca Astazou XVIII, 872 shp |
| Main Rotor Diameter | 37.7 ft |
| Tail Rotor Diameter | 3.0 ft |
| Empty Weight | 2,900 lbs |
| Gross Weight | 5,291 lbs |
| Height | 10.2 ft |
| Length | 42.6 ft |
| Width | 6.9 ft |

Bell 206L-III

| | |
|---------------------|-------------------------------|
| Power Plant | (1) Allison 250-C30P, 650 shp |
| Main Rotor Diameter | 37.0 ft |
| Tail Rotor Diameter | 5.42 ft |
| Empty Weight | 2,200 lbs |
| Gross Weight | 4,150 lbs |
| Height | 10.25 ft |
| Length | 42.7 ft |
| Width | 7.7 ft |

Bell 222UT

| | |
|---------------------|---|
| Power Plant | (2) Lycoming LTS 101-750C, 684 shp each |
| Main Rotor Diameter | 42 ft |
| Tail Rotor Diameter | 6.88 ft |
| Empty Weight | 4,874 lbs |
| Gross Weight | 8,250 lbs |
| Height | 10.42 ft |
| Length | 50 ft |
| Width | 10.25 ft |

Bell 412

| | |
|---------------------|--------------------------|
| Power Plant | (2) P&W PT6T-3B, 900 shp |
| Main Rotor Diameter | 46.0 ft |
| Tail Rotor Diameter | 8.5 ft |
| Empty Weight | 6,470 lbs |
| Gross Weight | 11,900 lbs |
| Height | 15.1 ft |
| Length | 56.0 ft |
| Width | 9.3 ft |

Hughes 500E

| | |
|---------------------|-------------------------------|
| Power Plant | (1) Allison 250-C20B, 420 shp |
| Main Rotor Diameter | 26.35 ft |
| Tail Rotor Diameter | 4.58 ft |
| Empty Weight | 1,455 lbs |
| Gross Weight | 3,000 lbs |
| Height | 9.18 ft |
| Length | 30.8 ft |
| Width | 6.07 ft |

Hughes 530F

| | |
|---------------------|------------------------------|
| Power Plant | (1) Allison 250-C30, 650 shp |
| Main Rotor Diameter | 27.4 ft |
| Tail Rotor Diameter | 4.75 ft |
| Empty Weight | 1,585 lbs |
| Gross Weight | 3,100 lbs |
| Height | 9.18 ft |
| Length | 32.06 ft |
| Width | 6.07 ft |

Westland WG-30

| | |
|---------------------|--------------------------|
| Power Plant | (2) GE CT7-2B, 1,615 shp |
| Main Rotor Diameter | 43.67 ft |
| Tail Rotor Diameter | 8.0 ft |
| Empty Weight | 7,875 lbs |
| Gross Weight | 12,800 lbs |
| Height | 15.5 ft |
| Length | 46.67 ft |
| Width | 10.17 ft |
